

# Section 1

# Introduction to Bayesian Statistics

# A motivating example

- ▶ Student 1 will write down a number and then flip a coin
- ▶ **If the flip is heads**, they will honestly tell student 2 if the number is even or odd
- ▶ **If the flip is tails**, they will lie
- ▶ Student 2 will then guess if the number is odd or even
- ▶ Let  $\theta$  be probability that student 2 correctly guesses whether the number is even or odd

# A motivating example

Before we start,

1. What's your best guess about  $\theta$ ?
2. What's the probability that  $\theta$  is greater than a half?

# A motivating example

The class has \_\_\_\_ successes in \_\_\_\_ trials. In light of these data,

1. What's your best guess about  $\theta$ ?
2. What's the probability that  $\theta$  is greater than a half?

# Frequentist approach

- ▶ A **frequentist procedure** quantifies uncertainty in terms of *repeating the process that generated the data many times*
- ▶ The parameters  $\theta$  are fixed and unknown
- ▶ The sample (data)  $Y$  is random
- ▶ A frequentist would **never** say  $\text{Prob}(\theta > 0) = 0.60$  because  $\theta$  is not a random variable
- ▶ All probability statements should be made about randomness in the data

# Frequentist approach

- ▶ A **frequentist** procedure quantifies uncertainty in terms of *repeating the process that generated the data many times*
- ▶ For an illustration see <http://www.rossmanchance.com/applets/ConfSim.html>
- ▶ A **statistic**  $\hat{\theta}$  is a summary of the sample
- ▶ For example, the sample mean  $\hat{\theta} = \bar{X}$  is a statistic, and it is an **estimator** of the population mean  $\theta = \mu$
- ▶ The distribution of  $\hat{\theta}$  that arises from repeating the process that generated the data many times is its **sampling distribution**
- ▶ A frequentist would **never** say “the distribution of  $\mu$  is Normal(4.2,1.2)”

# Frequentist approach

- ▶ A **frequentist** procedure quantifies uncertainty in terms of *repeating the process that generated the data many times*
- ▶ A **95% confidence interval**  $(l, u)$  is
- ▶ A frequentist would **never** say “the probability that the true mean is in the interval  $(3.4, 4.5)$  is 0.95”

# Frequentist approach

- ▶ A **frequentist** procedure quantifies uncertainty in terms of *repeating the process that generated the data many times*
  - ▶ A common approach for testing a hypothesis is to reject the null if a test statistic exceeds a threshold
  - ▶ For example, we might reject  $\mathcal{H}_0 : \mu \leq 0$  in favor of the alternative  $\mathcal{H}_1 : \mu > 0$  if  $\bar{X} > T$
  - ▶ A **p-value** is
- 
- ▶ A frequentist would **never** say “the probability that the null hypothesis is true is 0.03”

# Frequentist approach

There is currently an intense discussion of the merits of the p-value in the scientific community:

- ▶ <http://www.nature.com/news/scientific-method-statistical-errors-1.14700>
- ▶ <http://fivethirtyeight.com/features/not-even-scientists-can-easily-explain-p-values>
- ▶ <http://fivethirtyeight.com/features/science-isnt-broken/>
- ▶ <http://www.tandfonline.com/doi/pdf/10.1080/01973533.2015.1012991>

# How about a frequentist answer these questions?

Before we start:

1. What's your best guess about  $\theta$ ?
2. What's the probability that  $\theta$  is greater than a half?

After we have observed some trials:

1. What's your best guess about  $\theta$  now?
2. What's the probability that  $\theta$  is greater than a half now?

# The Bayesian approach

- ▶ Bayesians also view  $\theta$  as fixed and unknown
- ▶ However, we express our uncertainty about  $\theta$  using probability distributions
- ▶ The distribution before observing the data is the **prior distribution**
- ▶ Example:  $\text{Prob}(\theta > 0.5) = 0.6$ .
- ▶ Probability statements like this are intuitive (to me at least)
- ▶ This is subjective in that people may have different priors (there is also a field called objective Bayes)

# The Bayesian approach

- ▶ Our uncertainty about  $\theta$  is changed (hopefully reduced) after observing the data
- ▶ The **Likelihood function** is the distribution of the observed data given the parameters
- ▶ This is the same likelihood function used in a maximum likelihood analysis
- ▶ Therefore, when the prior information is weak a Bayesian and maximum likelihood analysis are similar

# The Bayesian approach

- ▶ The uncertainty distribution of  $\theta$  after observing the data is the **posterior distribution**

- ▶ **Bayes theorem** provides the rule for updating the prior

$$f(\theta|Y) = \frac{f(Y|\theta)f(\theta)}{f(Y)}$$

- ▶ In words: Posterior  $\propto$  Likelihood  $\cdot$  prior
- ▶ A key difference between Bayesian and frequentist statistics is that all inference is conditional on the single data set we observed  $Y$

## Back to the example

- ▶ Say we observed  $Y = 60$  successes in  $n = 100$  trials
- ▶ The parameter  $\theta \in [0, 1]$  is the true probability of success
- ▶ In most cases we would select a prior that puts probability on all values between 0 and 1
- ▶ If we have no relevant prior information we might use the prior

$$\theta \sim \text{Uniform}(0, 1)$$

so that all values between 0 and 1 are equally likely

- ▶ This is an example of an **uninformative prior**

# Posterior distribution

- ▶ The likelihood is  $Y|\theta \sim \text{Binomial}(n, \theta)$
- ▶ The uniform prior is  $\theta \sim \text{Uniform}(0, 1)$
- ▶ Then it turns out the posterior is

$$\theta|Y \sim \text{Beta}(Y + 1, n - Y + 1)$$

# Bayesian learning: $Y = 60$ and $n = 100$

# Beta prior

- ▶ The uniform prior represents prior ignorance
- ▶ To encode prior information we need a more general prior
- ▶ The beta distribution is a common prior for a parameter that is bounded between 0 and 1
- ▶ If  $\theta \sim \text{Beta}(a, b)$  then the posterior is

$$\theta|Y \sim \text{Beta}(Y + a, n - Y + b)$$

Prior 1:  $\theta \sim \text{Beta}(1, 1)$

## Prior 2: $\theta \sim \text{Beta}(0.5, 0.5)$

## Prior 3: $\theta \sim \text{Beta}(2, 2)$

## Prior 4: $\theta \sim \text{Beta}(20, 1)$

# Plot of different beta priors

# Plots of the corresponding posteriors

# Sensitivity to the prior

$a$	$b$	Prior			Posterior		
		Mean	SD	$P > 0.5$	Mean	SD	$P > 0.5$
1	1	0.50	0.29	0.50	0.60	0.05	0.98
0.5	0.5	0.50	0.50	0.50	0.60	0.05	0.98
2	2	0.50	0.22	0.50	0.60	0.05	0.98
20	1	0.95	0.05	1.00	0.66	0.04	1.00

# Summary

- ▶ The first three priors give essentially the same results
- ▶ Say the objective is to test  $\mathcal{H}_0 : \theta \leq 0.5$  versus  $\mathcal{H}_A : \theta > 0.5$
- ▶ In these three cases we can say that after observing the data the probability of the null is only 0.02 and the alternative is 50 times more likely than the null
- ▶ The final prior strongly favored large  $\theta$  and gave different results
- ▶ How would we argue this analysis is useful?

# Advantages of the Bayesian approach

- ▶ Bayesian concepts (posterior prob of the null) are arguably easier to interpret than frequentist ideas (p-value)
- ▶ We can incorporate scientific knowledge via the prior
- ▶ Excellent at quantifying uncertainty in complex problems (e.g., missing data, correlation, etc.)
- ▶ In some cases the computing is easier
- ▶ Provides a framework to incorporate data/information from multiple sources

# Disadvantages of Bayesian methods

- ▶ Picking a prior is subjective (we'll study objective priors)
- ▶ Procedures with frequentist properties are desirable (we'll study the frequentist properties of Bayesian methods)
- ▶ Computing can be slow or unstable for hard problems
- ▶ Less common/familiar
- ▶ Nonparametric methods are challenging
